**The explanation of functionality of an application:**

The files of an application work together in order to run the application without any major errors and make sure that the files have been set up correctly in an efficient way. But the most important files of the project are api, bulk-upload, app, server, validate, incidents-routes, and incidents-store, which are the technique methods to aid the application functionality. Api are used to fetch data between files inside the application, the bulk-upload JavaScript file is used to create a CSV file, allow users to select a CSV file, and upload it on the dashboard. and validate JavaScript file is used to validate input from a user to ensure the required input has been filled out. The purpose of the functions was to enhance incidents tracking system, maintain a stable APIs integration, and also CRUD operations to allow users to do with the files/documents in an application. These are the methods that support the development and the functionality of the application to ensure a working, stable application.
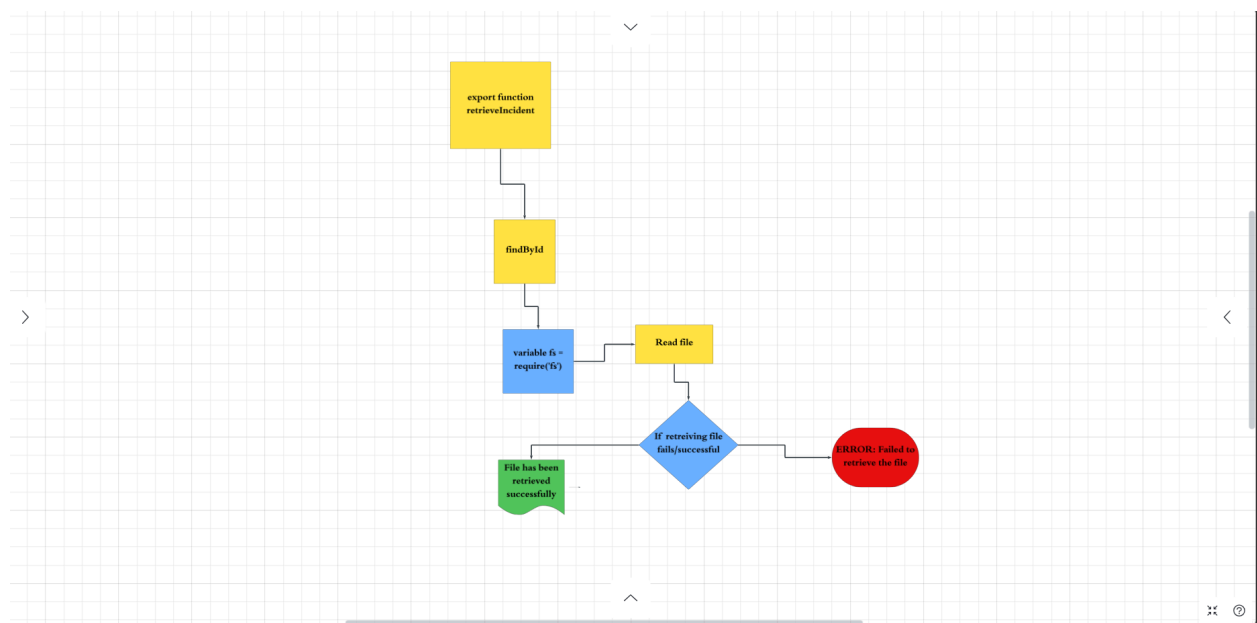

Create Incident functionality:

Update Incidents functionality:

Retrieve Incidents functionality:

Bulk-Upload incidents functionality:
